CELLULAR PAVINGS OF FIBERS OF CONVOLUTION MORPHISMS

BY THOMAS J. HAINES

Abstract. This article proves, in the case of split groups over arbitrary fields, that all fibers of convolution morphisms attached to parahoric affine flag varieties are paved by products of affine lines and affine lines minus a point. This applies in particular to the affine Grassmannian and to the convolution morphisms in the context of the geometric Satake correspondence. The second part of the article extends these results over \( \mathbb{Z} \). Those in turn relate to the recent work of Cass-van den Hove-Scholbach on the geometric Satake equivalence for integral motives, and provide some alternative proofs for some of their results.

1. Introduction and Main Results

Let \( G \) be a split connected reductive group over any field \( k \). Let \( W \) be the Iwahori-Weyl group of \( LG(k) = G(k((t))) \), and for each \( r \)-tuple \( w_* = (w_1, \ldots, w_r) \in W^r \) and choice of standard parahoric subgroup \( \mathcal{P} \subset LG(k) \) consider the convolution morphism

\[
m_{w_* \mathcal{P}} : X_{\mathcal{P}}(w_*) := X_{\mathcal{P}}(w_1) \times \cdots \times X_{\mathcal{P}}(w_r) \to X_{\mathcal{P}}(w_*)
\]

defined on the twisted product of Schubert varieties \( X_{\mathcal{P}}(w_*) \subset Fl_{\mathcal{P}} \) (see §2 and §3). Such morphisms have long played an important role in the geometric Langlands program and in the study of the geometry of Schubert varieties. For example, if \( w_* = (s_1, \ldots, s_r) \) is a sequence of simple affine reflections, \( w = s_1 \cdots s_r \) is a reduced word, and \( \mathcal{P} \) is the standard Iwahori subgroup \( B \), then \( X_B(s_*) \to X_B(w) \) is the Demazure resolution (of singularities) of \( X_B(w) \). If \( \mathcal{P} = L^+G \) is the positive loop group and \( w_* = \mu_* = (\mu_1, \ldots, \mu_r) \) is a tuple of cocharacters in \( G \), the corresponding convolution morphism is used to define the convolution of \( L^+G \)-equivariant perverse sheaves on the affine Grassmannian \( \text{Gr}_G = LG/L^+G \), and hence it plays a key role in the geometric Satake correspondence.

Numerous applications stem from the study of the fibers of convolution morphisms, their dimensions and irreducible components, and possible pavings of them by affine spaces or related spaces. We recall that a variety \( X \) is paved by varieties in a class \( \mathcal{C} \) provided that there exists a finite exhaustion by

fibers of uncompactified space paving of fibers of known which fibers are paved by affine spaces (see [Hai06, Question 3.9]). The existence of an affine LG/L does always hold. Turns out to usually fail (for examples, see Remarks 6.6 and 6.7 below). However, a weaker result Theorem 1.3. §

A weaker version of Corollary 1.2 was stated without proof in [dCHL18, Rem. 2.5.4]. The proof is cellular pavings [RS20, Def. 3.1.5]. We adopt a similar terminology and declare that they admit products of copies of Every fiber of any convolution morphism \( X_P(w_\bullet) \to X_P(w_\bullet) \) is paved by affine spaces. In the special case of a sequence of minuscule cocharacters \( w_\bullet = \mu_\bullet \) and the associated convolution morphism \( X_{L^+G}(\mu_\bullet) \to X_{L^+G}(\mu_\bullet) \) for the affine Grassmannian \( Gr_G = LG/L^+G \), this was proved in [Hai06, Cor. 1.2]. In general for the affine Grassmannian, it is not known which fibers are paved by affine spaces (see [Hai06, Question 3.9]). The existence of an affine space paving of fibers of \( m_{w_\bullet,P} \) in the general case seems to be an interesting open question – and the author is not aware of any counterexamples. One can consider the analogous question of when fibers of uncompactified convolution morphisms \( Y_P(w_\bullet) \to X_P(w_\bullet) \) are paved by affine spaces. This turns out to usually fail (for examples, see Remarks 6.6 and 6.7 below). However, a weaker result does always hold.

**Theorem 1.1.** Every fiber of a convolution morphism \( Y_P(w_\bullet) \to X_P(w_\bullet) \) is paved by finite products of copies of \( k^1 \) and \( k^1 - k^0 \).

As a corollary we obtain the following result on fibers of the usual convolution morphisms.

**Corollary 1.2.** Every fiber of any convolution morphism \( X_P(w_\bullet) \to X_P(w_\bullet) \) is paved by finite products of copies of \( k^1 \) and \( k^1 - k^0 \).

The previous two results show that the fibers in question are cellular k-schemes, in the sense of [RS20, Def. 3.1.5]. We adopt a similar terminology and declare that they admit cellular pavings. A weaker version of Corollary 1.2 was stated without proof in [dCHL18, Rem. 2.5.4]. The proof is given here in §8, §7, and §8.

One situation where paving by affine spaces is known is given by the following result.

**Theorem 1.3.** Suppose \( w_\bullet = s_\bullet = (s_1, s_2, \ldots, s_r) \) is a sequence of simple reflections with Demazure product \( s_\bullet = s_1 * s_2 * \cdots * s_r \). Then the fibers of \( X_G(s_\bullet) \to X_G(s_\bullet) \) are paved by affine spaces.

This theorem was proved in [dCHL18, Thm. 2.5.2]. However, here we give a different proof, which has the advantage that it can be easily adapted to prove the special case of Theorem 1.1 where \( P = B \) and every \( w_i \) is a simple reflection. This in turn is used to prove the general case of Theorem 1.1.

The results above should all have analogues at least for connected reductive groups \( G \) which are defined and tamely ramified over a field \( k((j)) \) with \( k \) perfect (see Remark 4.2). The proofs will necessarily be more involved and technical, and the author expects them to appear in a separate work.

In section 11, we extend all the preceding results over \( \mathbb{Z} \). We prove in that section the following result (Theorem 11.17), the second part of which recovers [CvdHS+ , Thm. 1.2].

**Theorem 1.4.** Assume \( G_\mathbb{Z} \supset B_\mathbb{Z} \supset T_\mathbb{Z} \) is a connected reductive group over \( \mathbb{Z} \) with Borel pair defined over \( \mathbb{Z} \). Consider a parahoric subgroup \( P_\mathbb{Z} \) and the associated Schubert schemes \( X_{P,\mathbb{Z}}(w) \subset \text{Fl}_{P,\mathbb{Z}} \). The convolution morphisms attached to \( w_\bullet = (w_1, \ldots, w_r) \in W^r \) may be constructed over \( \mathbb{Z} \)

\[
m_{w_\bullet, P_\mathbb{Z}} : X_{P,\mathbb{Z}}(w_\bullet) \to X_{P,\mathbb{Z}}(w_\bullet).
\]

and for any \( v \leq w_\bullet \), the fiber \( m_{w_\bullet, P_\mathbb{Z}}^{-1}(v \in P_\mathbb{Z}) \) has a cellular paving over \( \mathbb{Z} \). Furthermore for any standard parabolic subgroup \( P_\mathbb{Z} = M_\mathbb{Z} N_\mathbb{Z} \) and any pair \( (\mu, \lambda) \in X_*(T)^+ \times X_*(T)^+ \), the subscheme \( L^* M_\mathbb{Z} N_\mathbb{Z} X_{P,\mathbb{Z}}(\mu) \cap L^* G_\mathbb{Z} F_\mu \) of the affine Grassmannian \( G_{G,\mathbb{Z}} \) has a cellular paving over \( \mathbb{Z} \).

**Leitfaden:** Here is an outline of the contents of this article. In §2 and §3 we give our notation and recall the basic definitions related to convolution morphisms. The main idea of the proof of Theorem
1.1 is to prove it by induction on \( r \): one projects from the fiber onto the \( r - 1 \) term in the twisted product; then one needs to show that the image is paved by locally closed subvarieties, each of which has a \( C \)-paving, and over which the aforementioned projection morphism is trivial. The strategy of proof is given in more detail in §6.2. The required triviality statements are proved in §4 and §5. The core of the article is found in §6 – §8. First, Theorem 1.3 is proved in §6.2, and this proof is then adapted to prove the special case of Theorem 1.1 for \( \mathcal{P} = \mathcal{B} \) and all \( w \), simple reflections, in §6.3. This is used to deduce the special case of Theorem 1.1 with \( \mathcal{P} = \mathcal{B} \) in §7.2. Finally, the general case of Theorem 1.1 is proved in §7.3, using the previous special cases as stepping-stones. In §8 we quickly deduce Corollary 1.2 from Theorem 1.1. In §9 we give an application to structure constants for parahoric Hecke algebras. In §11 we develop all the needed machinery to extend the above results over \( \mathbb{Z} \). The paper ends with Errata for [dCHL18] in §12.

**Acknowledgments:** I express my thanks to Thibaud van den Hove, whose questions about [CvdHS+] prompted me to write up these results. I also thank him for helpful comments on an early version of this paper, and for giving me access to an advance copy of the revised version of [CvdHS+].

## 2. Notation

Generally speaking, we follow the same notation and conventions as [dCHL18]. Let \( G \) be a split connected reductive group over a field \( k \) with algebraic closure \( k^{\text{sep}} \). Fix a Borel pair \( G \supset B \supset T \), also split and defined over \( k \). This gives rise to the based absolute root system \((X^+(T) \supset \Phi, X_+(T) \supset \Phi^\vee, \Delta)\), the real vector space \( V = X_+(T) \otimes \mathbb{R} \), and the canonical perfect pairing \( \langle \cdot, \cdot \rangle : X^+(T) \times X_+(T) \to \mathbb{Z} \). The affine roots \( \Phi_{\text{aff}} = \{ a = a + n | a \in \Phi, n \in \mathbb{Z} \} \) are affine-linear functionals on \( V \). We denote the origin by \( 0 \in V \) and the \( B \)-dominant Weyl chamber \( \mathcal{C} = \{ v \in V | \langle a, v \rangle > 0, \forall a \in \Delta \} \) with apex at \( 0 \). We denote the set of dominant cocharacters by \( X_+(T)^+ := X_+(T) \cap \mathcal{C} \). We also fix the base alcove \( a \subset \mathcal{C} \) whose closure contains \( 0 \). The positive simple affine roots \( \Delta_{\text{aff}} \) are the minimal affine roots \( a = \alpha + n \) taking positive values on \( a \). We use the convention that \( \lambda \in X_+(T) \) acts on \( V \) by translation by \(-\lambda \). The finite Weyl group is the Coxeter group \((W_0, S)\) generated by the simple reflection \( \{ s_\alpha | s_\alpha \in S \} \) on \( V \), for \( \alpha \in \Delta \); the group \( W_0 \) fixes the origin \( 0 \). The extended affine Weyl group \( W = X_+(T) \rtimes W_0 \) acts on \( V \) and hence on the set \( \Phi_{\text{aff}} \) by precomposition. Let \((W_{\text{aff}}, S_{\text{aff}})\) denote the Coxeter group generated by \( S_{\text{aff}} \), the simple affine reflections \( s_\alpha \) for \( \alpha \in \Delta_{\text{aff}} \). It has a Bruhat order \( \leq \) and a length function \( \ell : W_{\text{aff}} \to \mathbb{Z}_{\geq 0} \).

Let \( \Omega \subset W \) be the subgroup stabilizing \( a \subset V \). The group decomposition \( W = W_{\text{aff}} \rtimes \Omega \) allows us to extend \( \leq \) and \( \ell \) from \( W_{\text{aff}} \) to \( W \), by declaring \( \Omega \) to be the set of length zero elements in \( W \).

Fix the field \( F = k((t)) \) and ring of integers \( O = k[[t]] \). The Iwahori-Weyl group \( N_G(T)\) may be naturally identified with \( W \). We choose once and for all lifts of \( w \in W_0 \) in \( N_G(T) \) and we lift \( \lambda \in X_+(T) \) to the element \( t^\lambda := \lambda(t) \in T(F) \). Altering these lifts by any elements in \( T(O) \) does not affect anything in what follows.

We define the loop group \( LG \) (resp., positive loop group \( L^+G \)) to be the group ind-scheme (resp., group scheme) over \( k \) representing the group functor on \( k \)-algebras \( LG(R) = G(R((t))) \) (resp., \( L^+G(R) = G(R[[t]]) \)). For a facet \( f \) contained in the closure of \( a \), we obtain the ‘standard” parahoric group scheme \( P_f \) (see [BT84, HR08]). We often write \( P := L^+P_f \), and regard this as a (standard) parahoric group in \( LG \). Note that \( L^+G = L^+P_0 \). The (standard) Iwahori subgroup will be denoted \( B := L^+P_a \). Let \( W_f := W_{P_f} \subset W_{\text{aff}} \) be the subgroup which fixes \( f \) pointwise; it is a Coxeter group generated by the simple affine reflections which fix \( f \). The Bruhat order \( \leq \) on \( W \) descends to a Bruhat order \( \leq \) on coset spaces such as \( W_{P_f}/W_{P_f} \). Let \( I_w \) denote the elements \( w \in W \) which are the unique \( \leq \)-maximal elements in their double cosets \( W_{P_f}wW_{P_f} \).

The partial affine flag variety is by definition the étale sheafification of the presheaf on the category \( \text{Aff}_k \) of affine schemes \( \text{Spec}(R) \) over \( k \) given by \( R \mapsto LG(R)/L^+P_f(R) \). It is represented by an ind-projective ind-scheme denoted simply by \( \text{Fl}_{P_f} = LG/L^+P_f \), and it carries a left action by \( P = L^+P_f \). Denote by \( e_{\text{pt}} \) its natural base point. It is well-known (see e.g. [HR08]) that for any two standard parahoric subgroups \( Q \) and \( P \), we have a natural bijection on the level of \( k \)-points and \( k^{\text{sep}} \)-points

\[
(2.1) \quad Q(k) \backslash \text{Fl}_{P_f}(k) = W_Q \backslash W_{P_f} = Q(k^{\text{sep}}) \backslash \text{Fl}_{P_f}(k^{\text{sep}}).
\]
The elements of Bruhat-Tits theory used in [HR08, Prop. 8, Rem. 9] work for split groups without any assumption that the residue field \(k\) is perfect (cf. also Remark 4.2). Alternatively, for split \(G\), (2.1) can be proved directly for any residue field \(k\) (including \(k\)), using BN-pair relations.

For \(w \in W\), let \(Y_{\mathcal{P}}(w)\) (resp. \(Y_{\mathcal{GP}}(w)\)) denote the \(\mathcal{P}\)-orbit (resp. \(\mathcal{B}\)-orbit) of \(w\) in \(W_{\mathcal{P}}\). When \(\mathcal{P} = \mathcal{B}\) we will often omit the subscripts. Define the Schubert variety \(X_{\mathcal{P}}(w)\) to be the Zariski closure of \(Y_{\mathcal{P}}(w) \subset W_{\mathcal{P}}\), endowed with reduced structure. Similarly, define \(X(w) = X_{\mathcal{B}}(w)\) and \(X_{\mathcal{GP}}(w)\).

In the part of this paper where we work over a field \(k\), the schemes which arise are finite-type separated schemes over \(k\) (not necessarily irreducible). We will always give them reduced structure, and we will call them "varieties". The morphisms of varieties we consider will always be defined over \(k\), and will usually be described on the level of points in an unspecified algebraic closure of \(k\).

3. Review of convolution morphisms

For \(w \in W\), define \(\overline{P_w\mathcal{P}} = \bigsqcup_{v \leq w} \mathcal{P}v\mathcal{P}\), where \(v\) ranges over elements \(v \in W_{\mathcal{P}}\backslash W/W_{\mathcal{P}}\). For any \(r\)-tuple \(w^r = (w_1, \ldots, w_r) \in W^r\), we define \(X_{\mathcal{P}}(w^r)\) to be the quotient of \(\mathcal{P}^r = (L^+P_t)^r\) acting on \(\overline{P_{w_1}\mathcal{P}} \times \overline{P_{w_2}\mathcal{P}} \times \cdots \times \overline{P_{w_r}\mathcal{P}}\) by the right action

\[(g_1, g_2, \ldots, g_r) \cdot (p_1, p_2, \ldots, p_r) := (g_1p_1g_1^{-1}g_2p_2g_2^{-1} \cdots g_r^{-1}p_r).\]

We define \(Y_{\mathcal{P}}(w^r)\) similarly, with each \(\overline{P_{w_i}\mathcal{P}}\) replaced by \(P_{w_i}\mathcal{P}\). The quotients should be understood as étale sheafifications of presheaf quotients on the category \(\text{Aff}_k\). It is well-known that \(X_{\mathcal{P}}(w^r)\) (resp., \(Y_{\mathcal{P}}(w^r)\)) is represented by an irreducible projective (resp., quasi-projective) \(k\)-variety.

We regard the above objects as "twisted products": \(X_{\mathcal{P}}(w^r) = X_{\mathcal{P}}(w_1) \times X_{\mathcal{P}}(w_2) \times \cdots \times X_{\mathcal{P}}(w_r)\) (resp., \(Y_{\mathcal{P}}(w^r) = Y_{\mathcal{P}}(w_1) \times Y_{\mathcal{P}}(w_2) \times \cdots \times Y_{\mathcal{P}}(w_r)\)), consisting of tuples \((g_1P, g_2P, \ldots, g_rP)\) such that \(g_i^{-1}g_1P \subset P_{w_i}\mathcal{P}\) for all \(1 \leq i \leq r\) (here \(g_0 = 1\) by convention).

We have a factorization of group functors \(\mathcal{U} = (U \cap \overline{U_{\mathcal{P}}}) \cdot (U \cap v\mathcal{P})\).

(a) We have a factorization of group functors

\[
\mathcal{U} = (\mathcal{U} \cap v\mathcal{U}_{\mathcal{P}}) \cdot (\mathcal{U} \cap v\mathcal{P}).
\]
(b) There is an isomorphism of schemes \( U \cap vU_P \cong \prod_a U_a \) where \( U_a \) ranges over the affine root groups corresponding to affine roots with \( a > 0 \) and \( v^{-1}a < 0 \), and the product is taken in any order.

Proof. This is [dCHL18, Prop. 3.7.4]. The proof over \( \mathbb{Z} \) given in Proposition 11.6 works here as well. \( \square \)

Remark 4.2. Usually the hypothesis that \( k \) is perfect is implicit in Bruhat-Tits theory and the theory of parahoric subgroups: all residue fields of the complete discretely-valued fields \( F \) one works over should be assumed to be perfect, so that Steinberg’s theorem applies to show that every reductive group over the completion \( \bar{F} \) of a maximal unramified extension of \( F \) is quasi-split. (This assumption on residue fields is missing from [HR08], and should be added. I am grateful to Gopal Prasad for pointing out this oversight.) Since we are assuming our group \( G \) is already split over \( k \), it is automatically quasi-split over \( k((t)) = k^{\text{perf}}((t)) \). Therefore we do not need to assume \( k \) is perfect when invoking Bruhat-Tits theory for \( G \). Note that the hypothesis that \( k \) is perfect appears to be used in the proof of [dCHL18, Prop. 3.7.4], since that proof relies on [dCHL18, Rem. 3.1.1]. However, the latter actually holds for all \( k \): we see the key point that \( B \) is \( k \)-triangularizable in the sense of [Spr, §14.1] by invoking [Spr, 16.1.1, 14.1.2] applied to \( B \).

Lemma 4.3. Assume that \( v \) is right-\( f \)-minimal, ie., it is the unique minimal element in its coset \( vW_{(f)} \), where \( W_{(f)} \) is the Coxeter subgroup of \( W_{\text{aff}} \) which fixes \( f \) pointwise. Then for any positive affine root \( a > 0 \), we have

\[
v^{-1}a < 0 \iff v^{-1}a < 0.
\]

Proof. The implication (\( \Rightarrow \)) uses only that \( f \) belongs to the closure of \( a \), and holds for any \( v \in W \).

Next we prove (\( \Leftarrow \)): Assuming \( v^{-1}a < 0 \), we wish to prove \( v^{-1}a < 0 \). Suppose on the contrary that \( v^{-1}a \geq 0 \). Combined with \( v^{-1}a < 0 \), we deduce \( v^{-1}a \neq 0 \), that is, \( v^{-1}s_a v \in W_{(f)} \). Since \( v \) is right-\( f \)-minimal and \( s_a v \in W_{(f)} \), we deduce that \( s_a v > v \). On the other hand, since \( a \) is positive on \( a \) and \( a \) is negative on \( a \), we see that \( f a \) and \( f a \) are on opposite sides of the affine root hyperplane \( H_a \), which means \( s_a v < v \), a contradiction. \( \square \)

Proposition 4.4. If \( v \in W \) is right-\( f \)-minimal, then we have isomorphisms

\[
Y_{BP}(v) \cong U \cap vU_P \cong U \cap \bar{U} \cong Y_{BS}(v).
\]

Proof. Since \( v \) normalizes \( T(O) \), we have \( Y_{BP}(v) = uvP/P \), which identifies with \( U \cap vU_P \) by Proposition 4.1(a) and by the fact that \( U_P \to F^P \) is an (open) immersion, see e.g. [dCHL18, Thm. 2.3.1]. This is identified with \( U \cap vU \) by Proposition 4.1(b) and Lemma 4.3. \( \square \)

Remark 4.5. The proof of Proposition 4.4 given here ultimately relies on the negative parahoric loop group introduced in [dCHL18]. Another proof which is more general and which avoids this reliance, is given in [HaRi12, Lem. 3.3]. We give the proof above because it is an almost immediate consequence of Proposition 4.1, which we need anyway to establish Proposition 5.1 below.

5. Stratified triviality of convolution morphisms

Proposition 5.1. The morphism \( m_{w_*} : X_P(w_*) \to X_P(w_*) \) is trivial over every \( B \)-orbit in its image.

Proof. Writing \( m := m_{w_*} \), we prove the triviality of the map \( m \) over \( B \)-orbits contained in its image. Assume \( Y_{BP}(v) \subset X_P(w_*) \). By Proposition 4.4, an element \( P' \in Y_{BP}(v) \) can be written in the form

\[
P' = uvP
\]

for a unique element \( u \in U \cap vU_P \).

We can then define an isomorphism

\[
m^{-1}(Y_{BP}(v)) \xrightarrow{\sim} m^{-1}(vP) \times Y_{BP}(v)
\]

by sending \((P_1, \ldots, P_{r-1}, uvP)\) to \((u^{-1}P_1, \ldots, u^{-1}P_{r-1}, vP)\times uvP \). Obviously the first factor belongs to \( m^{-1}(vP) \). \( \square \)
6. PAVING RESULTS FOR THE CASE $\mathcal{P} = B$

6.1. BN-pair relations and lemmas on retractions.

The following statements can be interpreted at the level of $k$ or $\bar{k}$-points, but we will suppress this from the notation. Recall that given $B_1 = g_1 B$, $B_2 = g_2 B$ and $w \in W$, we say the pair $(B_1, B_2)$ is in relative position $w$ (and we write $B_1 \overset{w}{\rightarrow} B_2$) if and only if $g_1^{-1} g_2 \in B w B$. We write $B_1 \overset{w}{\rightarrow} B_2$ if and only if $B_1 \overset{v}{\rightarrow} B_2$ for some $v \leq w$.

We have

$$Y_B(w) = \{ B' \mid B \overset{w}{\rightarrow} B' \} \quad \text{and} \quad X_B(w) = \{ B' \mid B \overset{w}{\leftarrow} B' \}.$$ 

The BN-pair relations hold for $v \in W$ and $s \in S_{aff}$:

$$B v B s B = \begin{cases} B v s B, & \text{if } v < vs, \\ B v B s B \cup B v B, & \text{if } vs < v. \end{cases}$$

Note that for every $v \in W$ and $s \in S_{aff}$, there is an isomorphism $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cong \mathbb{P}^1$ and $\{ B' \mid v B \overset{w}{\leftarrow} B' \} \subset Y_B(v) \cup Y_B(vs)$.

Lemma 6.1. Suppose $s \in S_{aff}$ and $v \in W$.

(i) If $v < vs$, then $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cap Y_B(v) = \{ v B \} \cong \mathbb{A}^0$.

(ii) If $v \leq vs$, then $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cap Y_B(vs) \cong \mathbb{A}^1$.

(iii) If $vs < v$, then $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cap Y_B(v) \cong \mathbb{A}^1$.

(iv) If $vs < v$, then $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cap Y_B(vs) = \{ vs B \} \cong \mathbb{A}^0$.

Proof. This is obvious from properties of the retraction map from the building associated to $G$ onto the apartment corresponding to $T$, with respect to an alcove in that apartment. A reference for how such retractions “work” is [HKM, §6].

In a similar way, we get an analogous lemma.

Lemma 6.2. Suppose $s \in S_{aff}$ and $v \in W$.

(i) If $v < vs$, then $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cap Y_B(v) = \emptyset$.

(ii) If $v \leq vs$, then $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cap Y_B(vs) \cong \mathbb{A}^1$.

(iii) If $vs < v$, then $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cap Y_B(v) \cong \mathbb{A}^1 - \mathbb{A}^0$.

(iv) If $vs < v$, then $\{ B' \mid v B \overset{s}{\leftarrow} B' \} \cap Y_B(vs) = \{ vs B \} \cong \mathbb{A}^0$.

6.2. Proof of Theorem 1.3. Since $B$ is understood, we will write $Y(w_s)$ for $Y_B(w_s)$, and $X(w_s)$ for $X_B(w_s)$ in what follows. Let $s_* = (s_1, \ldots, s_r) \in S^r$. There is no requirement here that $s_1 \cdots s_r$ be reduced. Recall the subvariety $X(s_*) \subset (G/B)^r$ which consists of the $r$-tuples $(B_1, \ldots, B_r)$ such that $B_i \overset{s_i}{\rightarrow} B_i$ for all $i = 1, \ldots, r$ (with the convention that $B_0 = B$).

We are going to prove the paving by affine spaces of the fibers of the morphism

$$m : X(s_*) \rightarrow X(s_*) \subset G/B, \quad (B_1, \ldots, B_r) \mapsto B.$$ 

We proceed by induction on $r$. The case $r = 1$ is trivial, so we assume $r > 1$ and that the theorem holds for $r - 1$. Let $s_*^r := s_1 \cdots s_{r-1}$. Let $s_*^r = (s_1, \ldots, s_{r-1})$. By our induction hypothesis, the theorem holds for

$$m' : X(s_*^r) \rightarrow X(s_*^r), \quad (B_1, \ldots, B_{r-1}) \mapsto B_{r-1}.$$ 

Now suppose $v \leq s_*$, so that $v B \in \text{Im}(m)$. For an element $(B_1, \ldots, B_{r-1}, v B) \in m^{-1}(v B)$, we have

$$B \overset{v}{\rightarrow} B \overset{s_r}{\leftarrow} B.$$ 

It follows from the BN-pair relations that $B_{r-1} \in Y(v) \cup Y(v s_r)$. We consider the map

$$\xi : m^{-1}(v B) \rightarrow Y(v) \cup Y(v s_r),$$

$$(B_1, \ldots, B_{r-1}, v B) \mapsto B_{r-1}.$$
We will examine the subsets $\text{Im}(\xi) \cap Y(v)$ and $\text{Im}(\xi) \cap Y(vs_r)$. We will show that

(i) these subsets are affine spaces (either empty, a point, or $A^1$): one of them, denoted $A_1$, is closed in $\text{Im}(\xi)$, and the other, denoted $A_2$, is nonempty, open, and dense in $\text{Im}(\xi)$;

(ii) if $A_i \neq \emptyset$, then $A_i$ belongs to $\text{Im}(m')$: furthermore $\xi^{-1}(A_i) \cong m'^{-1}(A_i)$ under the obvious identification, and $\xi : \xi^{-1}(A_i) \to A_i$ corresponds to the morphism $m' : m'^{-1}(A_i) \to A_i$.

These facts are enough to prove Theorem 1.3. Indeed, applying $\xi^{-1}$ to the decomposition

$$\text{Im}(\xi) = A_1 \cup A_2$$

and using (ii) gives us a decomposition

$$m^{-1}(vB) = \xi^{-1}(A_1) \cup \xi^{-1}(A_2) = m'^{-1}(A_1) \cup m'^{-1}(A_2)$$

where the first is closed and the second is nonempty and open. By the induction hypothesis, the fibers of $m'$ are paved by affine spaces. Since $A_i$ is contained in a $B$-orbit, we see $m'$ is trivial over each $A_i$ by Proposition 5.1, and hence each $m'^{-1}(A_i)$ is paved by affine spaces. Thus $m^{-1}(vB)$ is paved by affine spaces.

To verify the properties (i,ii), we need to consider various cases. We start with two cases which arise from the following standard lemma about the Bruhat order (see e.g. [Hum, Prop. 5.9]).

**Lemma 6.3.** Let $(W, S)$ be a Coxeter group and $x, y \in W$ and $s \in S$. Then $x \leq y$ implies $x \leq ys$ or $xs \leq ys$ (or both).

Recall $v \leq s_*$ by assumption. The two cases we need to consider are

Case I: $s'_* < s'_*s_*$, so that $s_* = s'_*s_*$. Thus by Lemma 6.3, $v \leq s'_*$ or $vs_r \leq s'_*$.

Case II: $s'_*s_* < s'_*$, so that $s_* = s'_*$. Thus $v \leq s'_*$.

We will break each of these into subcases, depending on whether $v < vs_r$ or $vs_r < v$. We then consider further subcases depending on which of $v$ or $vs_r$ precedes $s'_*$ in the Bruhat order.

Case I.1: $v < vs_r$. So $v \leq s'_*$ is automatic. There are two subcases:

1.1a: $v < vs_r \leq s'_*$;
1.1b: $v \leq s'_*$ but $vs_r \not\leq s'_*$.

Case I.2: $vs_r < v$. So $vs_r \leq s'_*$ is automatic. There are two subcases:

1.2a: $vs_r < v \leq s'_*$;
1.2b: $vs_r \leq s'_*$ but $v \not\leq s'_*$.

Case II.1: $v < vs_r$. As $v \leq s'_*$ is automatic, there are two subcases:

II.1a: $v < vs_r \leq s'_*$;
II.1b: $v \leq s'_*$ but $vs_r \not\leq s'_*$.

Case II.2: $vs_r < v$. Here $vs_r \leq s'_*$ and $v \leq s'_*$, so there are no further subcases.

Consider any element $(B_1, \ldots, B_{r-1}, vB)$ in $m^{-1}(vB)$. As noted already above, we have $B \leftarrow vB \leftarrow B_{r-1}$. Then Lemma 6.1 tells us the shape of $\text{Im}(\xi) \cap Y(v)$ and $\text{Im}(\xi) \cap Y(vs_r)$ in all the cases enumerated above. We record the results in the following table.

<table>
<thead>
<tr>
<th>Case</th>
<th>$\text{Im}(\xi) \cap Y(v)$</th>
<th>$\text{Im}(\xi) \cap Y(vs_r)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>I.1a</td>
<td>$A^0$</td>
<td>$A^1$</td>
</tr>
<tr>
<td>I.1b</td>
<td>$A^0$</td>
<td>$A^0$</td>
</tr>
<tr>
<td>I.2a</td>
<td>$A^1$</td>
<td>$A^0$</td>
</tr>
<tr>
<td>I.2b</td>
<td>$\emptyset$</td>
<td>$A^0$</td>
</tr>
<tr>
<td>II.1a</td>
<td>$A^0$</td>
<td>$A^1$</td>
</tr>
<tr>
<td>II.1b</td>
<td>$A^0$</td>
<td>$\emptyset$</td>
</tr>
<tr>
<td>II.2</td>
<td>$A^1$</td>
<td>$A^0$</td>
</tr>
</tbody>
</table>

In each case it is clear which piece should be labelled $A_1$ or $A_2$. This proves the main part of (i,ii); the other assertions are clear. This completes the proof of Theorem 1.3.

**Remark 6.4.** Each $A^1$ appearing in the table may be identified with a suitable affine root group $U_{\alpha+n}$, the $k$-group with $k$-points

$$U_{\alpha+n}(k) = \{u_\alpha(xt^n) \mid x \in k\},$$
where \( u_\alpha : G_a \to G \) is the root homomorphism corresponding to the root \( \alpha \). For example, consider Case I.1a. Then \( \text{Im}(\xi) \cap Y(vs_r) \) is \( \{ B_{r-1} | vB^{s_r}B_{r-1} \} \). Each such \( B_{r-1} \) can be expressed as \( B_{r-1} = vus_rB \) for a unique \( u \in \mathcal{U} \cap s_r\mathcal{U}_B \). Now use Proposition 4.1(b).

6.3. **Proof Theorem 1.1 in a special case.** We will now prove Theorem 1.1 in the case where \( \mathcal{P} = \mathcal{B} \) and \( w_i = s_i \) is a simple reflection for all \( 1 \leq i \leq r \). The argument is by induction on \( r \), as in the previous subsection. We consider the analogues \( p \) and \( p' \) of the morphisms \( m \) and \( m' \)

\[
p : Y(s_*) \to X(s), \quad (B_1, \ldots, B_{r-1}, B_r) \mapsto B_r
\]

and for \( vB \) in the image of \( p \), we consider the map

\[
\xi^0 : p^{-1}(vB) \to Y(v) \cup Y(vs_r)
\]

\[
(B_1, \ldots, B_{r-1}, vB) \mapsto B_{r-1}.
\]

The locally triviality of \( p \) over \( \mathcal{B} \)-orbits in its image still holds, and similarly for \( p' \) (see the proof of Proposition 5.1), and it suffices to establish the analogues of (i, ii) above. We consider the same cases as above, and we list the possibilities for \( \text{Im}(\xi^0) \cap Y(v) \) and \( \text{Im}(\xi^0) \cap Y(vs_r) \) in the table below, determined in each case with the help of Lemma 6.2.

<table>
<thead>
<tr>
<th>Case</th>
<th>( \text{Im}(\xi^0) \cap Y(v) )</th>
<th>( \text{Im}(\xi^0) \cap Y(vs_r) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>I.1a</td>
<td>( 0 )</td>
<td>( A^1 ) or ( \emptyset )</td>
</tr>
<tr>
<td>I.1b</td>
<td>( 0 )</td>
<td>( \emptyset )</td>
</tr>
<tr>
<td>I.2a</td>
<td>( A^1 - A^0 ) or ( \emptyset )</td>
<td>( A^0 ) or ( \emptyset )</td>
</tr>
<tr>
<td>I.2b</td>
<td>( 0 )</td>
<td>( A^0 ) or ( \emptyset )</td>
</tr>
<tr>
<td>II.1a</td>
<td>( 0 )</td>
<td>( A^1 ) or ( \emptyset )</td>
</tr>
<tr>
<td>II.1b</td>
<td>( 0 )</td>
<td>( \emptyset )</td>
</tr>
<tr>
<td>II.2</td>
<td>( A^1 - A^0 ) or ( \emptyset )</td>
<td>( A^1 ) or ( \emptyset )</td>
</tr>
</tbody>
</table>

Let us explain the meaning of entries such as "\( A^1 - A^0 \) or \( \emptyset \)" for example in the entry in case I.2a for \( \text{Im}(\xi^0) \cap Y(v) \). Note that \( v \leq s_r \) implies that \( Y(v) \subset \text{Im}(m') \), but \( Y(v) \subset \text{Im}(p') \) is not automatic. However, since \( p' \) is \( \mathcal{B} \)-equivariant we either have \( Y(v) \cap \text{Im}(p') = \emptyset \), or \( Y(v) \subset \text{Im}(p') \). If \( Y(v) \cap \text{Im}(p') = \emptyset \), the table entry is \( \emptyset \). If \( Y(v) \subset \text{Im}(p') \), the intersection \( \text{Im}(\xi^0) \cap Y(v) \) is precisely the part of \( Y(v) \) which is exactly of relative position \( s_r \) from \( vB \), and this identifies with \( A^1 - A^0 \) in the case where \( vs_r < v \).

The analogues of (i,ii) above hold, except that here, both \( A_1 \) and \( A_2 \) can be empty, and when nonempty the larger subset can be either \( A_0 \), \( A^1 - A^0 \), or \( A^1 \). The morphism \( p' \) is trivial over every \( \mathcal{B} \)-orbit in its image (comp Proposition 5.1), and by induction the nonempty fibers of \( p' \) are paved by finite products of copies of \( A^1 \) and \( A^1 - A^0 \). Therefore the fibers of \( p \) also have the desired property. This proves Theorem 1.1 in the special case where \( \mathcal{P} = \mathcal{B} \) and each \( w_i \) is a simple reflection \( s_i \). □

**Remark 6.5.** As in Remark 6.4, each \( A^1 \) in the table may be identified with an affine root group \( U_{a+n} \), and each \( A^1 - A^0 \) may be identified with a suitable variety of non-identity elements \( U_{a+n} \).

For example, consider Case I.2a. Then \( \text{Im}(\xi^0) \cap Y(v) \) is \( \{ B_{r-1} | vB^{s_r}B_{r-1} \} \) \( \cap \) \( Y(v) \). We may write such \( B_{r-1} \) as

\[
B_{r-1} = vus_rB
\]

for a unique \( u \in \mathcal{U} \cap s_r\mathcal{U}_B \) such that \( u \neq e \). Now use Proposition 4.1(b).

**Remark 6.6.** In the cases I.2a and II.2, the \( A^0 \) piece is in the closure of the \( A^1 - A^0 \) piece, and it is tempting to consider the union of these as \( A^1 \). Indeed, if one ignores the possibility of \( \emptyset \) in cases I.2a and II.2, the table seems to show that in every case \( \text{Im}(\xi^0) \) is an affine space (\( \emptyset \), \( A^0 \), or \( A^1 \)), and one could ask whether the argument does not in fact prove (by induction again) that every fiber of \( p \) is paved by affine spaces. However, one cannot ignore the empty set, and in fact in Case II.2 it is possible to have \( \text{Im}(\xi^0) \cap Y(v) = A^1 \not\subset A^0 \), while \( \text{Im}(\xi^0) \cap Y(vs_r) = \emptyset \). Letting \( s \in S_{\text{aff}} \), this happens for \( s_* = (s_1, s_2) = (s, s) \) and \( v = s_2 = s \). This situation is reflected by the quadratic relation in the Iwahori-Hecke algebra \( T_s \ast T_s = (q-1)T_s + qT_1 \). In addition, even in a special situation where
Im(ξ⁰) is always an affine space, the affine space paving would remain elusive, as it is not clear that p' would be trivial over all of Im(ξ⁰) whenever it is not contained in single B-orbit.

Remark 6.7. The above remark “explains” why we cannot hope to improve Theorem 1.1 to assert that all fibers of Yp(ς•) → Yp(ς•) are paved by affine spaces. For a concrete example related to the affine Grassmannian Gr = LG/L+P₀ over a finite field k = ℤ_q, take G = SO(5), and let

\[ \mu_1 = \mu_2 = \mu_3 = \alpha_1^\vee + \alpha_2^\vee = (1,1), \]

where α_j are the two simple coroots of G. Here we use notation following the conventions of [Bou]. In [KLM], §8.5 it is shown that the Hecke algebra structure constant c_{μ_0}(q) (the coefficient of the unit element in the product 1_{K^\vee}, K * 1_{K^\vee}, K * 1_{K^\vee}, K for K = L^+P₀(ℤ_q)) satisfies c_{μ_0}(q) = q^5 − q. This shows that the fiber over the base point e₀ of Y_{L^+P₀(ς•)} → X_{L^+P₀(ς•)} cannot be paved by affine spaces over ℤ_q.

7. Proof of Theorem 1.1

7.1. Schubert cells in FlB as convolution spaces. If τs₁ ⋯ s_τ = w is a reduced expression, we sometimes write Y(τs₁ ⋯ s_τ) for Y(w). This Schubert cell has the following well-known moduli description of its k-points.

Lemma 7.1. Fix the reduced expression w = τs₁ ⋯ s_τ as above.

(a) Giving a k-point of Y(w) is equivalent to giving a k-point of τ⁻¹Y(w), which is equivalent to giving a sequence of Iwahori subgroups (B₀, B₁, ⋯, B_r) such that

\[ B =: B₀ \cdot s₁ B₁ \cdot s₂ B₂ \cdot s₃ \cdots \cdot s_r B_r. \]

(b) For any element y ∈ LG(k), giving a k-point of y⁻¹Y(w) is equivalent to giving a sequence of Iwahori subgroups (B₀, B₁, ⋯, B_r) such that

\[ y⁻¹B =: B₀ \cdot s₁ B₁ \cdot s₂ B₂ \cdot s₃ \cdots \cdot s_r B_r. \]

Proof. In both cases, note that τ normalizes the Iwahori B.

7.2. Proof of Theorem 1.1 for P = B. Consider the morphism pu•, B : YB(ς•) → XB(ς•). For each 1 ≤ i ≤ r, we choose a reduced expression

\[ w_i = τ_i s₁ \cdots s_{in_i} \]

for s_ij ∈ S_{aff} and τ_i ∈ Ω. Since conjugation by τ_i normalizes B, permutes S_{aff}, and preserves the Demazure product, we may reduce the study of fibers to the case where each τ_i = 1. Then we have

\[ w_• = s₁ \cdots s_{in₁} \cdots s_{in₂} \cdots \cdots s_{in_r} =: s_{••}. \]

By Lemma 7.1, the morphism pu•, B is identified with the morphism pu•, B : Y(s••) → Y(s••). By §6.3, its fibers possess the required pavings.

7.3. Proof of Theorem 1.1 in general. Let C be the class of varieties which are finite products of copies of A¹ and A¹ − A¹.

We consider the morphism p = pu•, P : YP(ς•) → XP(ς•), and suppose vP lies in the image. We prove that the fiber p⁻¹(vP) has a C-paving by induction on r. As before, consider the morphism p' : YP(w₁, ⋯, w_{r−1}) → FlP given by (P₁, P₂, ⋯, P_{r−1}) ↦ P_{r−1}, and, by a slight abuse, its restriction ξ⁰ = p'|p⁻¹(vP) : p⁻¹(vP) → FlP, defined by (P₁, ⋯, P_{r−1}, vP) ↦ P_{r−1}. We have

\[ \text{Im}(ξ⁰) = \text{Im}(p') \cap vYP(w_{r−1}). \]

We claim that for any y ∈ W with corresponding B-orbit YB(y), the intersection Im(ξ⁰) ∩ YB(y) is either empty, or has a C-paving. Then since such locally closed subsets cover Im(ξ⁰) and since p' is trivial over each such subset, the C-paving of p⁻¹(vP) will follow by our induction hypothesis applied to p'. Note that if Im(p') ∩ YB(y) is nonempty, then YB(y) ⊂ Im(p'), and we are trying to produce a C-paving of

\[ YB(y) \cap vYP(w_{r−1}). \]
We can pass to \( B \)-orbits by writing \( W_P w_r^{-1} W_P = \prod_{\eta_m} \eta_m W_P \), for \( \eta_m \in W \) a finite collection of right-\( f \)-minimal elements. We then have a locally closed decomposition \( Y_P(w_r^{-1}) = \prod_{\eta_m} Y_{B_P}(\eta_m) \). Thus we need to show that each

\[ Y_{B_P}(y) \cap vY_{B_P}(\eta_m) \]

has a \( C \)-paving. We may assume \( y \) is also right-\( f \)-minimal. Then by Lemma 4.4, this is isomorphic to

\[ Y_B(y) \cap vY_B(\eta_m). \]

This is turn is equal to the fiber over \( vB \) of the morphism \( Y_B(y)^{\infty}Y_B(\eta_m) \rightarrow X_B(y \ast \eta_m) \). But each fiber of this morphism has a \( C \)-paving by §7.2.

\[ \square \]

8. Proof of Corollary 1.2

This follows immediately from Theorem 1.1, as we have a decomposition into locally closed subvarieties

\[ (8.1) \]

\[ X_P(w_*) = \prod_{v_*} Y_P(v_*) \]

where \( v_* \) ranges over all tuples \((v_1, v_2, \ldots, v_r) \in W_P \backslash W/W_P \) such that \( v_i \leq w_i \) in the Bruhat order on \( W_P \backslash W/W_P \) for all \( i \). Thus the fiber has a corresponding decomposition, and the result follows from Theorem 1.1.

\[ \square \]

9. Application to structure constants for parahoric Hecke Algebras

Fix a nonarchimedean field \( F \) with ring of integers \( O_F \) and residue field \( k_F = F_q \). Let us suppose \( G \) is a split group over \( \mathbb{Z} \), and fix a Borel pair \( B \supset T \) in \( G \), also split and defined over \( \mathbb{Z} \). This gives rise to the extended affine Weyl group \( W \) defined using \( G \supset B \supset T \) (it agrees with the extended affine Weyl group attached to \( G_F \supset B_F \supset T_F \)). For any parahoric subgroup \( P \subset G(F) \), consider the parahoric Hecke algebra \( \mathcal{H}(G(F)//P) = C_c(P \backslash G(F)//P, \mathbb{C}) \), give the structure of a unital associative \( \mathbb{C} \)-algebra with convolution \( \ast \) defined using the Haar measure on \( G(F) \) giving \( P \) volume 1. Consider the \( \mathbb{C} \)-basis of characteristic functions \( f_w := 1_{P \backslash W/P} \) indexed by elements \( w \in W_P \backslash W/W_P \). We can represent such cosets by maximal length elements \( w \in fW^f \).

**Proposition 9.1.** For any \( w_1, w_2 \in fW^f \), we have

\[ f_{w_1} \ast f_{w_2} = \sum_{v \in fW^f} c_{w_1, w_2}^v(q)f_v \]

where the structure constant is a non-negative integer of the form

\[ c_{w_1, w_2}^v(q) = \sum_{a, b \in \mathbb{Z}_{\geq 0}} m_{a, b} q^a(q - 1)^b \]

for certain non-negative integers \( m_{a, b} \) which vanish for all but finitely many pairs \((a, b)\).

**Proof.** The combinatorics of parahoric Hecke algebras over characteristic zero local fields \( F \) are the same as those for \( F = F_q((t)) \) (the parahoric subgroups in each setting chosen to correspond to each other in the obvious way, suitably identifying apartments for \( G_F \supset T_F \) and \( G_{F_q((t))} \supset T_{F_q((t))} \) and facets therein – for a much more general statement, see [PZ13, 4.1.2]). Therefore we can assume \( F \) is of the latter form. Then note that \( c_{w_1, w_2}^v(q) \) is the number of \( F_q \)-rational points in the fiber over \( vP \) of the corresponding convolution morphism \( Y_P(w_1) \tilde{\times} Y_P(w_2) \rightarrow X_P(w_*) \). Thus the result follows from Theorem 1.1.

\[ \square \]

This gives rise to general parahoric variants (in the equal parameter case) of combinatorial results on structure constants for spherical affine Hecke algebras due to Parkinson [Par06, Thm. 7.2] and Schwer [Schw06]. By virtue of the Macdonald formula (see e.g. [HKP, Thm. 5.6.1]), the function \( P_\lambda \) considered (albeit with differing normalizations) by Parkinson and Schwer agrees up to an explicit normalizing factor with the Satake tranform \( f_\lambda^X \) of the basis elements \( f_\lambda = 1_{C_F(q)[t]} \rho_* G(F_q((t)) \) above, for any dominant \( \lambda \in X_*(T) \). In particular, Proposition 9.1 shows that suitably renormalized versions of the functions \( C_{\lambda \mu}^\nu \) appearing in [Schw06, Thm. 1.3] lie in \( \mathbb{Z}_{\geq 0}[q - 1] \).
10. Cellular paving of certain subvarieties in the affine Grassmannian

In this section we will restrict our attention to certain generalizations of the intersections containing the Mirkovic-Vilonen cycles in the affine Grassmannian. Let \( \mathcal{P} = \mathcal{P}_0 = L^+G \), and consider the affine Grassmannian \( \text{Gr}_G = \text{Fl}_\mathcal{P} \). We fix any standard parabolic subgroup \( P \supset B \) with Levi factorization \( P = MN \), for a Levi subgroup \( M \supset T \) and unipotent radical \( N \subset U \). Here \( B = TU \) is the Levi decomposition of the fixed Borel subgroup \( B \).

We abbreviate \( K = L^+G \) and note that the intersection \( K_M := K \cap M \subset LG \) can be identified with \( L^+M \). We define \( K_P := K_M \cdot LN \). This is a semidirect group ind-scheme over \( k \), since \( K_M \) normalizes \( LN \). For \( \lambda \in X_*(T) \), denote the corresponding point by \( x_\lambda := \lambda(t)e_P \in \text{Gr}_G(k) \).

Fix \( \mu \in X_*(T)^+ \). Recall [HKM, Def. 3.1], in which we declare \( \nu \in X_*(T) \) satisfies \( \nu \geq^P \mu \) provided that:

- \( \langle \alpha, \nu \rangle = 0 \) for all \( T \)-roots \( \alpha \) appearing in \( \text{Lie}(M) \);
- \( \langle \alpha, \nu + \lambda \rangle > 0 \) for all \( T \)-roots \( \alpha \) appearing in \( \text{Lie}(N) \) and for all \( \lambda \in \Omega(\mu) \).

Here \( \Omega(\mu) = \{ \lambda \in X_*(T) \mid \mu - w\lambda \) is a sum of positive coroots, for all \( w \in W_0 \} \). Also, let \( X_*(T)^+ = M \) be the cocharacters which are dominant for the roots appearing in \( \text{Lie}(B \cap M) \).

**Proposition 10.1.** If \( \nu \geq^P \mu \) for \( \mu \in X_*(T)^+ \), and if \( \lambda \in \Omega(\mu) \cap X_*(T)^{+M} \), then there is an equality of \( k \)-subvarieties in \( \text{Gr}_G \)

\[
(t^{-\nu}Kt^\nu)x_\lambda \cap Kx_\mu = K_Px_\lambda \cap Kx_\mu.
\]

**Proof.** The equality \( (t^{-\nu}Kt^\nu)x_\lambda \cap Kx_\mu = K_Px_\lambda \cap Kx_\mu \) follows on combining [HKM, Prop. 7.1] and [HKM, Lem. 7.3]. The desired equality without the closures follows formally from this one.  

The left hand side of (10.1) admits a cellular paving by Theorem 1.1. Indeed, we have

\[
(t^{-\nu}Kt^\nu)x_\lambda \cap Kx_\mu = p_{w_\mu}^{-1}(t^{-\nu}e_{L^+G}),
\]

for \( w_\mu = (t_\mu, t_{-\nu-\lambda}) \). Hence we deduce the following result.

**Corollary 10.2.** For \( \mu, \lambda \) as above, the variety \( L^+M LN x_\lambda \cap L^+Gx_\mu \) in \( \text{Gr}_G \) admits a cellular paving. In particular, for \( P = B \), the Mirkovic-Vilonen variety \( LUx_\lambda \cap L^+Gx_\mu \) admits a cellular paving.

Note that this applies to all pairs \( (\mu, \lambda) \in X_*(T)^+ \times X_*(T)^{+M} \): if the intersection is non-empty, then \( \lambda \in \Omega(\mu) \) is automatic, by [HKM, Lem. 7.2(b)].

11. Paving results over \( \mathbb{Z} \)

The goal of what follows is to extend the constructions and results above to work over \( \mathbb{Z} \). Because there is no building attached to a group over \( \mathbb{Z}[t] \), the main challenge is to give purely group theoretic arguments for certain results which are usually proved with the aid of buildings.

11.1. Basic constructions over \( \mathbb{Z} \). We shall recall the basic notions attached to groups over \( \mathbb{Z} \). One useful reference is [RS20, §4], but in places we have chosen a slightly different way to justify the foundational results (for example, we do not assume the existence of the Demazure resolutions over \( \mathbb{Z} \) – a result stated without proof in [Fal03] – and instead we construct them as a special case of the convolution morphisms over \( \mathbb{Z} \)).

We assume \( G \) is a reductive group over \( \mathbb{Z} \), more precisely, a smooth affine group scheme over \( \mathbb{Z} \) whose geometric fibers are connected reductive groups, and which admits a maximal torus \( T \) over \( \mathbb{Z} \), which is automatically split (see [Co14, §6.4, Ex. 5.1.4]). We fix a Borel pair over \( \mathbb{Z} \), given by \( G \supset B \supset T \) (Borel subgroups \( B \supset T \) exist, by e.g. [Co14, pf. of Thm. 5.1.13]). Following [RS20, §4], we have the usual objects: the standard apartment endowed with its Coxeter complex structure given by the affine roots, the base alcove \( a \) and other facets \( f \) therein, the Weyl group \( W_0 \), the Iwahori-Weyl group \( W \), the affine Weyl group \( W_{aff} \), and the stabilizer subgroups \( W_f \subset W_{aff} \). The Iwahori-Weyl group \( W = N_G(T)(\mathbb{Z}[t])/(T(Z[t])) \) can be identified with the extended affine Weyl group \( X_*(T) \times W_0 \) where using [Co14, Prop. 5.1.6] we may identify \( W_0 = N_G(T)(\mathbb{Z}[t])/(T(Z[t])) \). As \( X_*(T) \times W_0 \) remains unchanged upon base changing along \( \mathbb{Z} \) to \( k \) for any field \( k \), it inherits a Bruhat
order $\leq$ as in the classical theory over a field. Similarly, the apartment is canonically identified with the apartments attached to $(G_{\mathbb{Q}(t)}, T_{\mathbb{Q}(t)})$ or $(G_{\mathbb{Z}[t]}, T_{\mathbb{Z}[t]})$ for any prime number $p$.

We define in the obvious way the positive loop group $L^+G_{\mathbb{Z}}$ (a pro-smooth affine group scheme over $\mathbb{Z}$) and the loop group $LG_{\mathbb{Z}}$ (an ind-affine group ind-scheme over $\mathbb{Z}$). For representability, see e.g. [HR20, Lem. 3.2].

The following result is essentially due to Pappas and Zhu, and this precise form was checked jointly with Timo Richarz.

**Lemma 11.1.** Let $f$ be any facet of the apartment corresponding to $T$ in the Bruhat-Tits building of $G(\mathbb{Q}(t))$, and let $G_{\mathbb{Z}[t]}$ be the associated parahoric $\mathbb{Q}[t]$-group scheme with connected fibers and with generic fiber $G \otimes_{\mathbb{Z}} \mathbb{Q}(t)$. Then there exists a unique smooth affine fiberwise connected $\mathbb{Z}[t]$-group scheme $G_f$ of finite type extending $G_{\mathbb{Z}[t]}$ with the following properties:

1. There is an identification of $\mathbb{Z}(t)$-groups $G_f \otimes_{\mathbb{Z}[t]} \mathbb{Z}(t) = G \otimes_{\mathbb{Z}} \mathbb{Z}(t)$.
2. For every prime number $p$, the group scheme $G_f \otimes_{\mathbb{Z}[t]} \mathbb{F}_p[t]$ is the Bruhat-Tits group scheme with connected fibers for $G \otimes_{\mathbb{Z}} \mathbb{F}_p(t)$ associated with $f$.

**Proof.** This is proven in [PZ13, 4.2.2]. Note that the base ring in loc. cit. is the polynomial ring $\mathcal{O}[t]$ where $\mathcal{O}$ is discretely valued. The same proof remains valid over the base ring $\mathbb{Z}[t]$ using [BT84, 3.9.4].

For each $f$, we define the “parahoric” subgroup $L^+G_f \subset LG_{\mathbb{Z}}$, and we often abbreviate by writing $\mathcal{P}_f := L^+G_f$. This has the property that for each homomorphism $\mathbb{Z} \to k$ for $k$ a field, we have $\mathcal{P}_f \otimes_{\mathbb{Z}} k \cong \mathcal{P}_k$ where the latter is the object defined earlier when working over the field $k$. We define the (partial) affine flag variety

\[ Fl_{\mathcal{P}, \mathbb{Z}} = (LG_{\mathbb{Z}}/\mathcal{P}_\mathbb{Z})^{\text{ét}}, \]

the étale sheafification of the quotient presheaf on $\text{Aff}_{\mathbb{Z}}$. This is represented by an ind-projective ind-scheme over $\mathbb{Z}$; see [HR20, Cor. 3.11], where the proof is given for objects defined over $\mathcal{O}[t]$ for any Noetherian ring $\mathcal{O}$ — a similar proof works in our setting over $\mathbb{Z}[t]$.

We denote the base point in $Fl_{\mathcal{P}, \mathbb{Z}}$ by $e_{\mathcal{P}, \mathbb{Z}}$.

We have a notion of a negative parahoric loop group and a corresponding open cell in $Fl_{\mathcal{P}, \mathbb{Z}}$. We define $L^-G_{\mathbb{Z}} := \ker(L^+G_{\mathbb{Z}} \to G_{\mathbb{Z}})$, $t^{-1} \mapsto 0$, where $L^-G_{\mathbb{Z}}(R) = G(R[t^{-1}])$. Following [dCHL18], we define $L^-G_{\mathcal{P}, \mathbb{Z}} = L^-G_{\mathbb{Z}} \times \mathbb{U}_{\mathbb{Z}}$. Then for any facet $f$ in the closure of $\mathcal{A}$, we define the negative parahoric loop group

\[ L^-G_{f, \mathbb{Z}} := \bigcap_{w \in W_f} w(L^-G_{\mathcal{A}, \mathbb{Z}}), \]

the intersection being taken in $LG_{\mathbb{Z}}$.

**Lemma 11.2.** The multiplication map $L^-G_{f, \mathbb{Z}} \times L^+G_{f, \mathbb{Z}} \to LG_{\mathbb{Z}}$ is representable by a quasi-compact open immersion.

**Proof.** This is proved in the same way as [HLR, Lem. 3.6], which proves the analogous result when the base ring is a ring of Witt vectors $W$ instead of $\mathbb{Z}$; the same argument works for our group schemes $G_f$ over $\mathcal{D}_\mathbb{Z}$ over $D_{\mathbb{Z}} := \mathbb{Z}[t]$. We omit the details.

From now on, we often write $G$ for $G_f$ and $\mathcal{P}_{\mathbb{Z}}$ for $L^+G_f$.

We recall the interpretation of partial affine flag varieties in terms of suitable affines of torsors. For any ring $R$, denote $D_R = \text{Spec}(R[[t]])$ and $D^t_R = \text{Spec}(R((t)))$. Recall that we define the sheaf $\text{Gr}_G$ on $\text{Aff}_{\mathbb{Z}}$ to be the functor sending $R$ to the set $\text{Gr}_G(R)$ of isomorphism classes of pairs $(E, \alpha)$ where $E$ is a right $\text{étale}$ torsor for $G_{D_R} = G \times_{D_Z} D_R$ over $D_R$, and where $\alpha \in E(D^t_R)$, that is, an isomorphism of $G_{D_R}$-torsors $E_0|_{D^t_R} \cong E|_{D^t_R}$, where $E_0$ is the trivial $G_{D_R}$-torsor. The left action of $g \in LG(R)$ on $\text{Gr}_G(R)$ sends $(E, \alpha)$ to $(E, \alpha \circ g^{-1})$. Then $\text{Gr}_G(R) \cong Fl_{\mathcal{P}, \mathbb{Z}}(R)$, functorially in $R$ (see e.g. [HR20, Lem. 3.4]).

**Remark 11.3.** For the groups $G$ over $\mathbb{Z}$ we consider, one can show using negative parahoric loop groups that the morphism $LG_{\mathbb{Z}} \to Fl_{\mathcal{P}, \mathbb{Z}}$ has sections locally in the Zariski-topology, and hence for any semi-local ring $R$ we have $Fl_{\mathcal{P}, \mathbb{Z}}(R) = LG_{\mathbb{Z}}(R)/\mathcal{P}_{\mathbb{Z}}(R)$. This can be seen by reducing to the
case of fields, as in [RS20, §4.3]. One can also deduce it from a recent result of Česnavičius [Ces22, Thm. 1.7] that the affine Grassmannian $\text{Gr}_{G,\mathbb{Z}}$ agrees with the Zariski sheafification of the presheaf quotient $L^G_{\mathbb{Z}}/L^+G_{\mathbb{Z}}$. To use this to prove the corresponding result for a general parahoric $\mathcal{P}_Z$, one first deduces the result for $\mathcal{P}_Z = \mathcal{B}_Z$, using the lifting for $\mathcal{P}_Z = L^+G_{\mathbb{Z}}$ and the fact that the fiber of $\text{Fl}_{\mathcal{B}_Z} \to \text{Gr}_{G,\mathbb{Z}}$ over the base point is $(G/B)_{\mathbb{Z}}$ and $G \to (G/B)_{\mathbb{Z}}$ is Zariski locally trivial. Then finally one uses the topological surjectivity of $\text{Fl}_{\mathcal{B}_Z} \to \text{Fl}_{\mathcal{P}_Z}$ to prove that a cover given by translates of the big cell in the source maps to a cover of translates of the big cell in the target. In fact one can use translates $wL^- \g_{\alpha}e_{\mathcal{B}_Z}$ for $w \in W$ to cover $\text{Fl}_{\mathcal{B}_Z}$, thanks to the Birkhoff decomposition of $L^G$ over fields (see [Fal03, Lem. 4]). I am grateful to Thibaud van Hove for a clarifying discussion about this remark, which we shall not need in the rest of this article.

**Lemma 11.4.** Fix a ring $R$ and $(\mathcal{E}, \alpha) \in \text{Gr}_G(R)$. Then the presheaf $\text{Gr}_{G,\mathcal{E},\alpha}$ sending $\text{Spec}(R') \to \text{Spec}(R)$ to the set of isomorphism classes of pairs $(\mathcal{E}', \alpha')$ consisting of a $\mathcal{G}_{D_{R'}}$-torsor $\mathcal{E}' \to D_{R'}$ and an isomorphism of $\mathcal{G}_{D_{R'}}$-torsors $\alpha' : \mathcal{E}'_{D_{R'}} \sim \mathcal{E}_{D_{R'}}$ is representable by an ind-projective ind-flat ind-scheme over $R$.

**Proof.** If we fix a representative $(\mathcal{E}, \alpha)$ within its isomorphism class, then the map

$$(\mathcal{E}', \alpha') \mapsto (\mathcal{E}', \alpha' \circ \alpha)$$

is a well-defined isomorphism of presheaves $\text{Gr}_{G,\mathcal{E},\alpha} \sim \text{Gr}_G \times \text{Spec}(R)$. Now recall that $\text{Gr}_G$ is ind-flat over $\mathbb{Z}$ by adapting the proof of [HLR, Prop. 8.9], or by reducing to the case $\mathcal{P}_Z = L^+G_{\mathbb{Z}}$ and then invoking [HLR, Prop. 8.8].

### 11.2. Ingredients needed for paving over $\mathbb{Z}$

11.2.1. **Iwahori decompositions of $\mathcal{B}_Z$ and $\mathcal{U}_Z$.** Our choice of base Iwahori subgroup $\mathcal{B}_Z$ is compatible with our choice of Borel subgroup $B = TU$ over $\mathbb{Z}$ in the following sense: for any algebra $R$, we have

$$\mathcal{B}_Z(R) = \{ g \in L^+G_{\mathbb{Z}}(R) \mid \bar{g} \in B(R) \}$$

where $\bar{g}$ is the image of $g$ under the canonical projection $L^+G_{\mathbb{Z}}(R) \to G(R)$. We define the pro-unipotent radical $\mathcal{U}_Z \subset \mathcal{B}_Z$ by requiring $\mathcal{U}_Z(R)$ to be the preimage of $U(R)$ under the projection $g \mapsto \bar{g}$. Let $\mathcal{T}_Z$ denote the group scheme $\mathcal{T}_Z = L^+T_{\mathbb{Z}}$. Let $\mathcal{B} = \mathcal{T}U$ be the Borel subgroup such that $B \cap \mathcal{B} = T$. For any integer $m \geq 1$, let $L^{(m)}G_{\mathbb{Z}}(R)$ denote the kernel of the natural homomorphism $L^+G_{\mathbb{Z}}(R) \to G(R/t^mR)$. Write $T_{\mathbb{Z}}^{(1)} := L^{(1)}T_{\mathbb{Z}}$.

**Proposition 11.5.** The group schemes $\mathcal{B}_Z$ and $\mathcal{U}_Z$ possess Iwahori decompositions with respect to $B = TU$, that is, there are unique factorizations of functors

$$\begin{align*}
\mathcal{B}_Z &= (\mathcal{B}_Z \cap L\mathcal{U}_Z) \cdot \mathcal{T}_Z \cdot (\mathcal{B}_Z \cap L\mathcal{U}_Z) \\
\mathcal{U}_Z &= (\mathcal{U}_Z \cap L\mathcal{U}_Z) \cdot \mathcal{T}_Z^{(1)} \cdot (\mathcal{B}_Z \cap L\mathcal{U}_Z).
\end{align*}$$

**Proof.** First we note that the uniqueness in the decomposition follows from the uniqueness of the decomposition in the big cell in $U \cdot T \cdot U$ in $G$.

We shall prove only the first decomposition (the second is completely similar). Consider $g \in \mathcal{B}_Z(R)$, with reduction modulo $t$ given by $\bar{g} = \bar{b}$ for some $b \in B(R) \subset L^+\mathcal{B}_Z(R)$. Then $g^{(1)} := gb^{-1} \in L^{(1)}G_{\mathbb{Z}}(R)$, and it suffices to show this element lies in

$$(\mathcal{B}_Z \cap L^{(1)}\mathcal{U}_Z) \cdot \mathcal{T}_Z^{(1)} \cdot (\mathcal{B}_Z \cap L^{(1)}\mathcal{U}_Z).$$

The filtration $\cdots \subset L^{(m+1)}G_{\mathbb{Z}} \subset L^{(m)}G_{\mathbb{Z}} \subset \cdots \subset L^+G_{\mathbb{Z}}$ has abelian quotients isomorphic to $\text{Lie}(G)_{\mathbb{Z}} = \text{Lie}(\mathcal{U})_{\mathbb{Z}} \oplus \text{Lie}(T)_{\mathbb{Z}} \oplus \text{Lie}(U)_{\mathbb{Z}}$. We claim that we can write

$$g^{(1)} = \lim_{m \to \infty} u_m \cdot t_m \cdot u_m$$

with $u_m, t_m, u_m$ lying in the $R$-points of the appropriate factors of (11.4), and such that the limit converges in the $t$-adic topology. Indeed, decomposing the image modulo $t^2$ of $g^{(1)}$ in terms of the Lie algebra and lifting, we can write

$$g^{(1)} = \bar{u}^{(1,2)} \cdot g^{(2)} \cdot t^{(1,2)} \cdot u^{(1,2)}$$
Proof. There are only finitely many affine roots \( a \) such that \( U_{a,Z} \) is contained in \( U_{Z} \cap \mathfrak{u}_{P,Z} \), namely the finitely many \( a \) with \( a > 0 \) and \( v^{-1}a \not< 0 \). By the Iwahori decomposition Proposition 11.5 and the root group filtrations in \( U_{Z} \) and \( U_{Z} \), we easily see that there exist finitely many positive affine roots \( a_1, \ldots, a_N \) such that

\[
(11.5) \quad U_{Z} = U_{a_1,Z} \cdots U_{a_N,Z} (U_{Z} \cap \mathfrak{u}_{P,Z}).
\]

In what follows, we suppress the subscript \( Z \). Give a total order \( \preceq \) on the set of positive affine roots \( a_i \) in this list, by letting \( a \prec b \) if and only if \( a(x_0) < b(x_0) \) for a suitably general point \( x_0 \in a \).

Let \( r_1 \prec r_2 \prec \cdots \prec r_M \) be the totally order subset of the \( a_i \)'s with the property that \( v^{-1}r_i \not< 0 \). The root group \( U_{r_1} \) appears finitely many times in \((11.5)\). Starting from the left, we commute the first \( U_{r_1} \) to the left past any preceding \( U_{b} \)'s. By the commutator relations (e.g. [dCHL18, (3.6)]), in moving all the \( U_{r_1} \) groups all the way to the left, we introduce finitely many additional affine root groups \( U_{c} \) with \( r_1 \prec c \). Then we consider the part of the product which now involves only root groups in of the form \( U_{r_2}, \ldots, U_{r_M} \) and certain \( U_{c} \) with \( v^{-1}c \not< 0 \). Then we repeat the above process with \( r_2 \) in place of \( r_1 \). Continuing, we eventually move all the \( U_r \) factors with \( v^{-1}r < 0 \) all the way to the left. We have proved that

\[
(11.6) \quad \mathcal{U} = \prod_{r} U_r (\mathcal{U} \cap \mathfrak{u}_{P}).
\]

where \( r \) ranges over the affine roots with \( r > 0 \) and \( v^{-1}r < 0 \). We claim that the obvious inclusion \( \prod_{r} U_r \subset \mathcal{U} \cap \mathfrak{u}_{P} \) is an equality, and the resulting product is a decomposition. Both statements follow easily using the theory of the big cell, Lemma 11.2. \( \square \)

Corollary 11.7. The analogues over \( Z \) of Propositions 4.4 and 5.1 hold.

11.2.3. Schubert cells and Schubert schemes over \( Z \). Fix \( w \in W \) and fix a lift \( \bar{w} \in N_{G}(\mathbb{Z}[\mathfrak{t}]) \) of \( w \). We usually suppress the dot from now on, since no construction depends on this choice. The group \( \mathcal{P}_{Z} \) acts on the left on \( \text{Fl}_{P,Z} \), we define the Schubert scheme \( X_{P,Z}(w) \subset \text{Fl}_{P,Z} \) to be the scheme-theoretic image of the morphism

\[
\mathcal{P}_{Z} \to \text{Fl}_{P,Z}, \quad p \mapsto \bar{w}e_{\mathcal{P}_{Z}}.
\]

Similarly we can define \( X_{Q_{P,Z}}(w) \) for any parahoric subgroup \( Q_{Z} \), in particular we have \( X_{B_{P,Z}} \).

We define \( Y_{P,Z}(w) \subset \text{Fl}_{P,Z} \) to be the étale sheaf-theoretic image of the morphism of sheaves \( \mathcal{P}_{Z} \to \text{Fl}_{P,Z}, \quad p \mapsto \bar{w}e_{\mathcal{P}} \), and as before we define similarly \( Y_{Q_{P,Z}} \) for any parahoric subgroup \( Q_{Z} \subset LG_{Z} \).
Lemma 11.8. Let $\mathcal{P}_Z \subset LG$ be the parahoric subgroup fixed above (similar statements apply to any $Q$-orbits in $Fl_{P,Z}$).

(a) The scheme $X_{P,Z}(w)$ is an integral scheme which is projective and faithfully flat over $\text{Spec}(Z)$, and $X_{P,Z}(w) \otimes Q = X_{P,Q}(w)$.

(b) The morphism $Y_{P,Z}(w) \to Fl_{P,Z}$ of étale sheaves factors canonically as

$$Y_{P,Z}(w) \to X_{P,Z}(w) \to Fl_{P,Z},$$

and the first morphism is represented by a quasi-compact open immersion of schemes.

(c) The scheme $Y_{P,Z}(w)$ is smooth over $\text{Spec}(Z)$, and its formation commutes with base change along an arbitrary homomorphism $Z \to R$.

Proof. The projectivity in (a) is proved in [RS20, Def 4.3.4, ff]. Part (b) can be proved by adapting the argument of [Ri16b, Cor. 3.14]. Part (c) holds since $Y_{P,Z}(w)$ is the orbit under a smooth group scheme over $Z$. Hence $Y_{P,Z}(w) \otimes Q = Y_{P,Q}(w)$.

The formation of scheme-theoretic image of a quasi-compact morphism commutes with flat base change (see [StaPro, Lem. 29.25.16]). So the generic fiber of $X_{P,Z}(w)$ is the schematic-closure of $Y_{P,Q}(w)$ in $Fl_{P,Q}$, that is, $X_{P,Z}(w) \otimes Q = X_{P,Q}(w)$. Now the flat closure of the latter in $X_{P,Z}$ contains the scheme-theoretic closure of $Y_{P,Z}(w)$, which is all of $X_{P,Z}(w)$. This shows that the latter is faithfully flat over $Z$. Clearly $X_{P,Z}(w)$ is irreducible since it is the scheme-theoretic image of a morphism with irreducible source. Moreover $X_{P,Z}(w)$ is reduced, since it is the flat-closure of a $Q$-variety.

11.2.4. Reduction to neutral element of $\Omega$. In the theory over fields $k$, it is easy to see that $\tau \in \Omega$ has the property that $\tau$ normalizes the standard Iwahori subgroup $B_k \subset LG_k$ corresponding to the base alcove $a$. We need to know that this remains true over $Z$.

Lemma 11.9. If $\tau \in \Omega$, then $^\tau B_Z = B_Z$ as subgroups of $LG_Z$.

Proof. The identification follows by the uniqueness characterization of the group scheme $G_{a,Z}$ in Lemma 11.1 and the fact that it holds after base change to every field $k$. □

11.2.5. Twisted products over $Z$. As above we fix $\mathcal{P}_Z = L^+G_{t,Z}$. Again abbreviate $G := G_{t,Z}$. Fix $r \in \mathbb{N}$ and consider the right action of $\mathcal{P}_Z^r$ on $LG_Z^r$ given by the same formula as (3.1).

Definition 11.10. We define the $r$-fold twisted product

$$\tilde{\text{Gr}}_G := LG_Z \times_{P_Z} LG_Z \times_{P_Z} \cdots \times_{P_Z} LG_Z / \mathcal{P}_Z :=: \text{Gr}_G \tilde{\times} \cdots \tilde{\times} \text{Gr}_G$$

to be the étale quotient sheaf for the presheaf $(LG_Z)^r / (\mathcal{P}_Z)^r$ defined above.

It is clear from the fact that every $G$-bundle over $D_R$ is trivializable over $D_{R'}$ for some étale ring extension $R \to R'$, that we can identify $\text{Gr}_G(R)$ with the set of equivalence classes of tuples

$$(\mathcal{E}_i, \alpha_i) = (\mathcal{E}_1, \ldots, \mathcal{E}_r; \alpha_1, \ldots, \alpha_r)$$

such that each $\mathcal{E}_i$ is a $G_{D_{R_i}}$-torsor over $D_{R_i}$ and the $\alpha_i : \mathcal{E}_{i-1}|_{D_{R_i}} \to \mathcal{E}_i|_{D_{R_i}}$ are isomorphisms of $G_{D_{R_i}}$-torsors over $D_{R_i}$ for all $i = 1, \ldots, r$ (with the convention that $\mathcal{E}_0$ is the trivial torsor).

Lemma 11.11. The sheaf $LG_Z \times_{P_Z} LG_Z \times_{P_Z} \cdots \times_{P_Z} LG_Z / \mathcal{P}_Z$ is represented by an ind-proper ind-scheme which is faithfully flat over $Z$.

Proof. We proceed by induction on $r$. The case $r = 1$ is clear: the ind-flatness of $\text{Gr}_G \to \text{Spec}(Z)$ is proved by an easy reduction to the case $\mathcal{P}_Z = L^+G_{t,Z}$, which is then handled by [HLR, Prop. 8.8].

Now assume $r > 1$ and that the result holds for $r - 1$-fold quotients. The projection onto the first factor gives a morphism

$$p : LG_Z \times_{P_Z} LG_Z \times_{P_Z} \cdots \times_{P_Z} LG_Z / \mathcal{P}_Z \to LG_Z / \mathcal{P}_Z.$$

Now the induction hypothesis and the proof of Lemma 11.4 shows that this morphism is representable by an ind-proper ind-flat ind-scheme, and hence the total space is represented by an ind-scheme.

Locally in the étale topology on the target, $p$ is locally trivial with flat fiber, hence is flat. It follows that the source of $p$ is flat over $Z$. 
It remains to prove the source of \( p \) is proper over \( \mathbb{Z} \). We know that ind-locally in the étale topology on the target, \( LG \to \text{Gr}_G \) has sections, and hence after passing to an étale cover \( p \) becomes Zariski-locally trivial with ind-proper over \( \mathbb{Z} \) fibers, by using translates of the big cell (see Lemma 11.2). Since properness descends along étale covers, we conclude that \( p \) is ind-proper, as desired.

Note that this argument becomes even simpler if we use the Zariski local triviality result of Česnavičius (see Remark 11.3) but we do not need this more sophisticated result.

Let \( w \in W \). Denoting the quotient morphism by \( q : LG \to \text{Fl}_{P,Z} \), note that \( \mathcal{P}_w \mathcal{P}_Z = q^{-1}(Y_{P,Z}(w)) \) (an equality of étale subsheaves of \( LG_Z \)), where by definition \( \mathcal{P}_w \mathcal{P}_Z \) denotes the étale sheaf quotient \( \mathcal{P}_Z \times_{w, \mathcal{P}_Z} \mathcal{P}_Z \) of \( \mathcal{P}_Z \times \mathcal{P}_Z \) by the right action of \( \mathcal{P}_Z \cap w \mathcal{P}_Z w^{-1} \) given by \((p, p') \cdot \delta = (p \delta, w^{-1} \delta^{-1} p \delta) \). In this vein, we define \( \mathcal{P}_w \mathcal{P}_Z := q^{-1}(X_{P,Z}(w)) \).

**Definition 11.12.** Let \( w_\bullet = (w_1, w_2, \ldots, w_r) \in W^r \). We define

\[
Y_{P,Z}(w_\bullet) := \mathcal{P}_{Z,w_1} \mathcal{P}_Z \times \mathcal{P}_{Z,w_2} \mathcal{P}_Z \times \cdots \times \mathcal{P}_{Z,w_r} \mathcal{P}_Z / \mathcal{P}_Z = Y_{P,Z}(w_1) \times Y_{P,Z}(w_2) \times \cdots \times Y_{P,Z}(w_r)
\]

\[
X_{P,Z}(w_\bullet) := \mathcal{P}_{Z,w_1} \mathcal{P}_Z \times \mathcal{P}_{Z,w_2} \mathcal{P}_Z \times \cdots \times \mathcal{P}_{Z,w_r} \mathcal{P}_Z / \mathcal{P}_Z = X_{P,Z}(w_1) \times X_{P,Z}(w_2) \times \cdots \times X_{P,Z}(w_r)
\]

to be the étale quotient schemes as in Definition 11.10.

**Lemma 11.13.** The sheaves \( X_{P,Z}(w_\bullet) \) and \( Y_{P,Z}(w_\bullet) \) are represented by integral schemes which are finite type and flat over \( Z \). Moreover, \( X_{P,Z}(w_\bullet) \) is proper over \( \mathbb{Z} \).

**Proof.** The proof goes by induction on \( r \), in the same manner as Lemma 11.11. \( \square \)

11.2.6. Demazure morphisms and closure relations over \( \mathbb{Z} \). We need to construct the Demazure resolutions over \( Z \). This is stated without proof in [Fal03] and is implicit in some literature (e.g. [PR08, RS20]) but we think some extra discussion is needed.

For \( s \in S_{af} \), let \( G_{s,Z} := G_{s}, \) where \( f \) is the facet fixed by \( s \). Let \( \mathcal{P}_{s,Z} = L^s G_{s,Z} \). We have \( \mathcal{P}_{s,Z} = B_Z \cup B_s Z B_Z \) as schemes (to show this we use Lemma 11.8(c), and the fact that the inclusion \( B_Z \cup B_s Z B_Z \to \mathcal{P}_{s,Z}(R) \) is surjective when \( R \) is any field, but we warn that this equality fails for general \( R \), in particular for \( R = \mathbb{Z} \)). We have an identification \( \mathcal{P}_Z^1 = \mathcal{P}_{s,Z}/B_Z \). Furthermore, the foregoing shows we have an open immersion \( A^1_N = B_s Z B_Z/ B_Z \to \mathcal{P}_Z^1 \) with closed complement \( A^0_N = B_Z/B_Z \hookrightarrow \mathcal{P}_Z^1 \). The BN-pair relations hold:

**Lemma 11.14.** For any \( w \in W \) and \( s \in S_{af} \), we have equalities of sub-ind-schemes in \( LG_Z \)

\[
B_Z w s B_Z B_Z = \begin{cases} B_Z w s B_Z, & \text{if } w < ws \\ B_Z w B_Z \cup B_Z w s B_Z, & \text{if } w s < w. \end{cases}
\]

**Proof.** Both cases are proved by induction on \( \ell(w) \). The first case follows from the case of fields and Lemma 11.8(c). For the second case, it is enough to prove the result for \( w = s \). But \( B_Z s B_s B_Z = B_Z s B_Z \cup B_Z = \mathcal{P}_{s,Z} \) follows because \( \mathcal{P}_{s,Z} \) is a group subscheme of \( LG_Z \) and \( sB_Z s \not\subset B_Z \). \( \square \)

Let \( w = s_1 \ldots s_r \) be a reduced word in \( W \). Consider the Demazure morphism given by projecting to the final coordinate

\[
m_{w_\bullet} : D(s_\bullet)_Z := \mathcal{P}_{s_1,Z} \times_{B_Z} \mathcal{P}_{s_2,Z} \times_{B_Z} \cdots \times_{B_Z} \mathcal{P}_{s_r,Z}/B_Z \to X_{B,Z}(w).
\]

The image lies in \( X_{B,Z}(w) \) by flatness and properness, and by the fact that this holds over \( Q \). By the BN-pair relations, it gives an isomorphism over \( Y_{B,Z}(w) \). Furthermore, it implies the closure relations

\[
(11.7) \quad X_{P,Z}(w) = \prod_v Y_{P,Z}(v)
\]

where \( v \in W_P \setminus W/W_P \) is such that \( v \leq w \) in the Bruhat order on \( W_P \setminus W/W_P \). In particular, we see \( \mathcal{P}_w \mathcal{P}_Z = \mathcal{P}_Z \mathcal{P}_V \mathcal{P}_Z \). Here and in (11.7) the union indicates a union of locally closed subschemes, and every subscheme appearing is reduced by construction.

With the existence of Demazure resolutions over \( \mathbb{Z} \) in hand, one can prove the following result by copying the argument of [HLR, Prop. 3.4] (Demazure resolutions over \( \mathbb{Z} \) are used to prove that Schubert varieties attached to simply-connected groups over a field \( k \) are normal, following the argument in [PR08, §9]).
Corollary 11.15. For any field \( k \), \( (X_{P,Z}(w) \otimes_Z k)_{\text{red}} = X_{P,k}(w) \). Further, \( X_{P,Z}(w) \otimes_Z k \) is reduced if and only if \( X_{P,k}(w) \) is normal.

11.2.7. Convolution morphisms over \( \mathbb{Z} \). Given the BN-pair relations involving subschemes of \( LG_Z \), we have the following.

Lemma 11.16. For any \( w_* = (w_1, w_2, \ldots, w_r) \in W^r \) with Demazure product

\[
  w_* := f_{w_1}^* f_{w_2}^* \cdots f_{w_r}^*,
\]

we have the convolution morphisms and uncompactified convolution morphisms over \( \mathbb{Z} \):

\[
  m_{w_*, P_*} : X_{P,Z}(w_*) \to X_{P,Z}(w_*)
  \quad \text{and} \quad
  p_{w_*, P_*} : Y_{P,Z}(w_*) \to X_{P,Z}(w_*)
\]

11.3. Main results over \( \mathbb{Z} \). The following theorem gives the \( \mathbb{Z} \)-versions of Corollaries 1.2 and 10.2.

Theorem 11.17. In the notation above, for any \( v \in W \) the fiber \( m_{w_*, P_*}(v \cdot P_*) \) has a cellular paving over \( \mathbb{Z} \), that is, it is paved by finite products of \( A^1 \) and \( A^0 \). Further, for every standard parabolic subgroup \( P_* = M_* N_* \subseteq G_* \), and every pair of cocharacters \( (\mu, \lambda) \in X_*(T)^+ \times X_*(T)^{+w} \), the scheme \( L^+ M_* L N_* x_{\lambda} \cap L^+ G_* x_{\mu} \) in \( \text{Gr}_{G_*} \) has a cellular paving over \( \mathbb{Z} \).

Note that the second statement gives an alternate proof of a recent result of Cass-van den Hove-Schoelbach, namely [CvdHs+, Thm. 1.2].

Proof. The proofs of the results over fields can be directly imported to the context over \( \mathbb{Z} \), using in particular Corollary 11.7, Lemma 11.9, Lemma 11.14, and equation (11.7). With these tools in hand, the proof over fields works over \( \mathbb{Z} \) with no changes. Note that we do not really need the language of retractions at any point in the proof: every fact justified using retractions is equivalent to a purely group-theoretic statement. See for example Remarks 6.4 and 6.5.

12. errata for [dCHL18]

We take this opportunity to point out a few minor mistakes in [dCHL18]. In [dCHL18, Prop. 3.10.2], we stated that all Schubert varieties \( X_P(w) \) in partial affine flag varieties \( F_P \) are normal. This is true for classical Schubert varieties (those contained in \( G/P \) for a parabolic subgroup \( P \) in \( G \)) but is false in general. Pappas and Rapoport proved in [PR08] that normality does hold for all affine Schubert varieties attached to \( G \) over a field \( k \), as long as the characteristic of \( k \) is coprime to the order of the Borovoi fundamental group \( \pi_1(G_{der}) \) (see [Bo98]). However, when \( \text{char}(k) \) divides \( |\pi_1(G_{der})| \), it is proved in [HLR, Thm. 2.5] that most Schubert varieties in \( F_P \) are not normal.

The normality of Schubert varieties is invoked in [dCHL18, Cor. 4.1.4] to prove that the convolution space \( X_P(w_*) \) is normal. This also fails in general, but is true when \( \text{char}(k) \nmid |\pi_1(G_{der})| \). In addition, normality of Schubert varieties is used in one of the proofs in [dCHL18] that the fibers of convolution morphisms \( X_P(w_*) \to X_P(w_*) \) are geometrically connected. More precisely, a normality hypothesis plays a role in [dCHL18, Prop. 4.4.4], which in turn is used to prove the geometric connectedness of the fibers in [dCHL18, Cor. 4.4.5]. This proof is not valid in general, but is valid, again, under the hypothesis \( \text{char}(k) \nmid |\pi_1(G_{der})| \). Fortunately, in [dCHL18, Thm. 2.2.2], another proof of the geometric connectedness of the fibers is given, which does not rely on any normality of Schubert varieties.

Furthermore, the polynomials \( F_{p,v}(q) \) appearing in [dCHL18, Eqn. (2.1)] were defined incorrectly as the Poincaré polynomials of the fibers \( p^{-1}(vB) \). They are rather the functions

\[
  F_{p,v}(q) = \text{tr}(\text{Frob}_q, \sum_i (-1)^i H^i(p^{-1}(vB), IC_{X_B(w_*)})).
\]

The fact that \( F_{p,v}(q) \in \mathbb{Z}_{\geq 0}[q] \) is not \textit{a priori} obvious, but it follows from [dCHL18, Eqn. (2.1)].
